

So I, so basically in terms of what this system has, this system will have this, obviously the front-end component of how a user interacts with it, right? So let's just call it, we have the front-end, okay? Then this front-end needs its back-end, okay? And behind this back-end, the run, the magic of the run is your Hermes, okay? Hermes, okay? And Hermes obviously will have, will be running in parallel, each, like, you know, there will be like hundred employees, actually, like, have you used Trigger.dev? It's like it's an async platform. So the thing is that, kabhi kabhi aisa hota hai ki jo Hermes agent hai, wo bahut database heavy ho jata hai. So if you connect that to a Trigger.dev like platform, wo kya karta hai, wo server load kam kar leta hai. It is free also. And kya hota hai ki every run you can monitor ki aisa run chal raha hai. It's like a UI dashboard. So we could connect Trigger.dev with this, and then it will be very, because for my startup I do that and it's very, like we have a lot of images and... If we have experience with that, no brainer, we can do that. So, so far I only see these components, and obviously, like the back-end is taking care of the persistent storage and all those things. So are you comfortable with managing ke bhai, how is user interacting with system? Yeah. Okay? For you, do you have a preference between back-end and Hermes? I actually, mujhe pata hai main kuch bhi kar loonga. I don't know, I'll just figure out. Will you figure out the Hermes thing or... Hermes I have used it, so I can tell you like how to. Basically, one of us will do this, one of us will do this. What is back-end? Back-end, you remember outside I was telling you... Oh, that run, oh... Like each user, each user, multi-tenancy, and making sure that the Hermes runs are running well, like triggered, spinning well. So it's more of orchestration. And Hermes run is building this... Yeah, I think wo single instance mein karta hoon, wo tenancy. Okay, perfect. So, let's do this. Yeah, and can you just start from start? Can you just start with the whole thing so that... Okay, perfect. So, to summarize, aur wo aajaega to... Okay. To summarize, we have this platform, agentic platform called Goal Achiever. The platform is achieving any goal, multi-month goal that we give them. There are two kinds of ways in which the platform can take information. There is a synchronous manner. For example, if I am having a meeting, a walkthrough, and I have like 10 walkthroughs in a week, I want to make sure that before the walkthroughs, I am prepared so there will be pre-synthesis of information so that it is curated for that meeting, for me, for the agenda. Then there will be post-synthesis after the walkthrough meeting to make sure that whatever we discussed is not only understood but contextualized in the company knowledge. Some assumptions that we are making is the platform knows my role, my responsibility, my scope, the platform, I have articulated my multi-month goal with clarity and objectivity in that platform, and the platform, the assumption is the platform has access to all company knowledge, like GitHub repos, GDrive, Confluence, etc., Slack, etc. Coming back to the flow, in the synchronous flow we discussed, we will do a pre-synthesizing, post-synthesizing. After post-synthesizing, what's important is it is generating a bunch of artifacts. Some, like, you know, if I am an engineering manager or if I am an IT auditor and I have done a walkthrough with a product engineering team, I want to generate a C4-style systems diagram to understand what's happening. I want to generate similar visualizations, mental models, which also span across walkthroughs and across systems to help me build my mental understanding, etc. Once I have done the synthesis and generated the artifact, the platform needs to do two actions for me. It has to make sure this run throughs or takes care of all the follow-ups. Follow-ups require reminders. As we get close to the ETA and reminders or commitments, it needs to help me nudge the stakeholders. And finally, the follow-ups job is to help me close the loop. Then there is the action item that comes

out of the synthesis. Action items are, if there were decisions made, it should be recorded in an ADR which is stored in the same manner, same place. It should be able to generate tickets for me so that I can action on them. Finally, this platform is supposed to help me with end-of-week summary and start-of-week alignment so that I know exactly what I need to achieve this week, which is in context with the larger multi-month goal. The hierarchy of the system looks like it has a multi-month goal. Each goal requires many meetings, async, sorry, synchronously and sometimes an async discussion. Every time I want to plug the platform into respective synchronous or asynchronous threads, each thread will trigger a run. A run in the platform usually goes through the same steps that I mentioned. There is the synthesizer, there is the artifact generator, the follow-up agent, the AI action item agent, and finally, the weekly summarizer agent. Each level of this hierarchy will have their own memory. Agents will have their own local memory. Each run will have memory across agents. And finally, we will be building a more long-term multi-month goal level memory. So we have that. We call the local memory M1, the run memory M2, and the goal memory M3. I think that's all that we discussed. This one we discussed? Yeah, the assumptions.

we are creating this for the hackathon below. go through the whole doc and give me the scope, mental models and a mvp idea under 4 hours.
